

## 3.8: Thermochemical Equations

Energy changes which accompany chemical reactions are almost always expressed by thermochemical equations, such as

$$\begin{aligned} \mathrm{C}H_4(g) + 2\mathrm{O}_2(g) \rightarrow \mathrm{CO}_2(g) + 2\mathrm{H}_2\mathrm{O}(l) & (25\,^\circ\mathrm{C}, 1 \text{ atm pressure}) \\ \Delta H_m = & -890 \mathrm{kJ} \end{aligned} \tag{3.8.1}$$

which is displayed on the atomic level below. To get an idea of what this reaction looks like on the macroscopic level, check out the flames on the far right.

Here the  $\Delta H_m$  (delta H subscript m) tells us whether heat energy is released or absorbed when the reaction occurs as written, and also enables us to find the actual quantity of energy involved. By convention, if  $\Delta H_m$  is *positive*, heat is *absorbed* by the reaction; i.e., it is **endothermic**. More commonly,  $\Delta H_m$  is *negative* as in Eq. 3.8.1, indicating that heat energy is *released* rather than absorbed by the reaction, and that the reaction is **exothermic**. This convention as to whether  $\Delta H_m$  is positive or negative looks at the heat change in terms of the matter actually involved in the reaction rather than its surroundings. In the reaction in Eq. 3.8.1, the C, H, and O atoms have collectively lost energy and it is this loss which is indicated by a negative value of  $\Delta H_m$ .

It is important to notice that  $\Delta H_m$  is the energy for the reaction as written. In the case of Equation 3.8.1, that represents the formation of 1 mol of carbon dioxide and 2 mol of water. The quantity of heat released or absorbed by a reaction is proportional to the amount of each substance consumed or produced by the reaction. Thus Eq. 3.8.1 tells us that 890.4 kJ of heat energy is given off *for every mole of* CH<sub>4</sub> which is consumed. Alternatively, it tells us that 890.4 kJ is released *for every 2 moles of* H<sub>2</sub>O produced. Seen in this way,  $\Delta H_m$  is a conversion factor enabling us to calculate the heat absorbed or released when a given amount of substance is consumed or produced. If q is the quantity of heat absorbed or released and n is the amount of substance involved, then

$$\Delta H_{
m m} = rac{q}{n}$$

## ✓ Example 3.8.1 : Heat Energy

How much heat energy is obtained when 1 kg of ethane gas, C<sub>2</sub>H<sub>6</sub>, is burned in oxygen according to the equation:

$$2C_2H_6(g) + 7O_2(g) \rightarrow 4CO_2(g) + 6H_2O(l)$$

with  $\Delta H_m = -3120$  kJ.

## **Solution**

The mass of  $C_2H_6$  is easily converted to the amount of  $C_2H_6$  from which the heat energy q is easily calculated by means of Eq. (2). The value of  $\Delta H_m$  is -3120 kJ per per 2 mol  $C_2H_6$ . The road map is

$$m_{ ext{C}_2 ext{H}_6} \stackrel{M}{\longrightarrow} n_{ ext{C}_2 ext{H}_6} \stackrel{\Delta H_m}{\longrightarrow} q$$

so that

$$\begin{split} q \ &= 1 \times 10^3 \; \mathrm{g} \; \mathrm{C_2H_6} \times \frac{1 \; \mathrm{mol} \; \mathrm{C_2H_6}}{30.07 \; \mathrm{g} \; \mathrm{C_2H_6}} \times \frac{-3120 \; \mathrm{kJ}}{2 \; \mathrm{mol} \; \mathrm{C_2H_6}} \\ &= -51 \; 879 \; \mathrm{kJ} = -51.88 \; \mathrm{MJ} \end{split}$$

By convention, a negative value of q corresponds to a release of heat energy by the matter involved in the reaction.

The quantity  $\Delta H_m$  is referred to as an **enthalpy change for the reaction**. In this context the symbol  $\Delta$  (delta) signifies change in" while H is the symbol for the quantity being changed, namely the enthalpy. We will deal with the enthalpy in some detail in Chap. 15. For the moment we can think of it as a property of matter which increases when matter absorbs energy and decreases when matter releases energy.

It is important to realize that the value of  $\Delta H_m$  given in thermochemical equations like 3.8.1 or ???? depends on the physical state of both the reactants and the products. Thus, if water were obtained as a gas instead of a liquid in the reaction in Eq. 3.8.1, the value of  $\Delta H_m$  would be different from -890.4 kJ. It is also necessary to specify both the temperature and pressure since the value of  $\Delta H_m$  depends very slightly on these variables. If these are not specified they usually refer to 25°C and to normal atmospheric pressure.

Two more characteristics of thermochemical equations arise from the law of conservation of energy. The first is that writing an equation in the reverse direction changes the sign of the enthalpy change. For example,

$$\mathrm{H_2O}(l) 
ightarrow \mathrm{H_2O}(g) \ \Delta \mathrm{H}_m = 44 \mathrm{\ kJ}$$

In the image above, the flames input energy into the water, giving it the energy necessary to transition to the gas phase. Since flames provide the energy for the phase transition, this is an endothermic reaction (energy is absorbed).

tells us that when a mole of liquid water vaporizes, 44 kJ of heat is absorbed. This corresponds to the fact that heat is absorbed from your skin when perspiration evaporates, and you cool off. Condensation of 1 mol of water vapor, on the other hand, gives off exactly the same quantity of heat.

$$ext{H}_2 ext{O}(g) 
ightarrow ext{H}_2 ext{O}(l) \ \Delta ext{H}_m = -44 ext{kJ}$$

It's counterintuitive, but the common summer occurrence seen above is actually exothermic. Since the reaction isn't highly exothermic (like the combustion of CH<sub>4</sub>), we find it hard to associate with a release of energy. Thermodynamics allows us to better understand on a micro level energy changes like this one.

To see why this must be true, suppose that  $\Delta H_m$  [Eq. (4a)] = 44 kJ while  $\Delta H_m$  [Eq. (4b)] = -50.0 kJ. If we took 1 mol of liquid water and allowed it to evaporate, 44 kJ would be absorbed. We could then condense the water vapor, and 50.0 kJ would be given off. We could again have 1 mol of liquid water at 25°C but we would also have 6 kJ of heat which had been created from nowhere! This would violate the law of conservation of energy. The only way the problem can he avoided is for  $\Delta H_m$  of the reverse reaction to be equal in magnitude but opposite in sign from  $\Delta H_m$  of the forward reaction. That is,

$$\Delta H_m$$
 forward =  $-\Delta H_m$  reverse
